

Replication code “Solving Serial Acquirer Puzzles” to get Tables

Macias, A. J., P. R. Rau, and A. Stouraitis. 2023. Solving serial acquirer puzzles. *Review of Corporate Finance Studies*. Forthcoming.

From main text:

3.1. Data

We obtain our sample of acquisitions of U.S. targets (public, private, and subsidiary firms) announced by U.S. public acquirers during 1989-2018 from the Thomson One’s Securities Data Company (SDC) database. We require that the bidder seeks to acquire more than 50% ownership of the target, and that the Center for Research in Security Prices (CRSP) and COMPUSTAT provide information for the acquirer. We obtain stock return and accounting data for the universe of U.S. publicly listed firms from CRSP and COMPUSTAT as of the quarter prior to the announcement date. To alleviate truncation concerns at the start and end of our sampling window, and to avoid concerns about the coverage of SDC in the early 1980s (Netter, Stegemoller, and Wintoki 2011), we require that (i) the acquirer has not conducted any acquisition in the 4 years prior to the start of our sample period (1985-1988); and (ii) that the acquirer conducts its first acquisition at the latest by the year 2016. Our initial sample consists of 55,482 mergers and acquisitions conducted by 8,640 unique acquirers. Our sample increases to 27,813 unique firms (239,120 firm-year observations) when we include firms that do not conduct any acquisitions within our sample period.

3.2. Classifying serial acquirers

We use cluster analysis to classify acquirers into one of four distinct types that we denote as loners, occasional acquirers, sprinters, and marathoners. Our classification is based on three common-sense dimensions. We perform the cluster analysis (and reclassify acquirers) annually, using data for the past 5 years. Based on three dimensions (total number of acquisitions over the past 5 years, number of acquisition blocks and average intensity), we conduct a k -median cluster analysis to classify acquirers into different categories, within 5-year rolling windows (starting with 1989-1993 and ending with 2014-2018) as depicted in Figure 1.

0. Preliminary code to set up the dataset that contains the serial acquirer classification used in the rest of the analysis.

Since our data comes from proprietary databases (e.g., Compustat, CRSP, SDC) we will focus on submitting the replication code assuming that any reader with access to such databases would be able to create the original merged dataset from such sources instead of us uploading such data that our licenses do not allow us to upload open to the public for people without such licenses. The paper describes the commonly used filters and merging methods used to generate the dataset from such proprietary databases. First, we run the other replication code [**“Replication code Serial Acquirers to get the serial acquirer classification “**] with selected extracts of the original whole dataset where convenient to exemplify how the code would work with the whole dataset in order to get the serial acquirer classification. Once anyone runs such replication code, the replication code in this file for the actual tables should be straightforward (e.g., running OLS or logit regressions in Stata, getting descriptive statistics in SAS, etc.)

In general, we handle and clean the data in SAS and run the econometric analysis in Stata. Depending on the type of descriptive statistics, we use either SAS or Stata. In several tables we build the tables in Excel with the appropriate format using the output from the SAS or Stata. The analysis is based on two levels, namely, deal and firm-year level. To avoid sharing an individual dataset for each table, the shared datasets might already contain some of the defined variables, hence dropping some of them to be used in the provided shared sub-sample would be needed to see how such variable is used. We left in the dataset several variables used in the robustness and ancillary analyses. The main variables of interest are defined in the appendix or its labels are self-explanatory based on the analysis and corresponding code.
